**Keywords:** Common bean, qualitative traits, quantitative traits, cluster analysis, landraces.

A total of 84 common bean (Phaseolus vulgaris L.) accessions were collected from different areas of Tanzania serving as source of germplasm. Nineteen agromorphological traits of 84 common bean accessions were assessed to analyze the variability as a core objective for this study. Among all the accessions, 40.48% were characterized by indeterminate bush with moderate climbing ability and pods distributed evenly up to the plant habitus followed by 36.9%. Similarly, 14.29% were the genotypes with indeterminate bush with semi-climbing main stem and branches habitus genotypes. Also, 14.29% were the genotypes with the indeterminate bush with prostrate, and 7.14% were the genotypes with indeterminate bush with erect branches habitus while 1.19% were the genotypes with determinate bush least. Phonological, quantitative and qualitative traits were evaluated and their scores were subjected to principal component analysis and cluster analysis. The phylogenetic tree demonstrated 2 major clusters which were further divided into sub-clusters. Principal component analysis accounted for the accumulative variance of 35.78% revealing morphological variation highly attributed with variables which had greater than 0.2 Eigen values. The study demonstrated low morphological variation among the genotypes and emphasized the need to broaden genetic variability of the common bean in Tanzania. The results of this study can be used to select the valuable breeding material for use. Besides, molecular markers can be deployed to assess further the variability and diversity of these genotypes.

#### INTRODUCTION

The common bean (*Phaseolus vulgaris* L.; 2n = 2x =22) is a self-pollinated crop and the most widely grown pulse food crop of a high nutritive value for people worldwide including Eastern and Southern Africa (CIAT, 2005). Based on archaeological observations from Peru and South-Western United States in the late 19th century, it was concluded that the common bean was originated from the two identified viz. the Andean and the centers Mesoamerican. The former common bean is characterized by large seeded kidney, cranberry, and many snap beans among others. The latter one is represented by medium and small seeded pinto, pink, black, white, and some snap beans (Beebe et al., 2001). Domestication and subsequent evolution of the common bean affected the reduction of variability in morphological, physiological and other traits, compared with wild bean (Gepts and Debouck, 1991). Thus, diverse common bean accessions represent valuable resources for the improvement of common bean, since co-adapted genes of different accessions can convey similar response to natural and artificial selection pressure if selected for a specific trait.

In Tanzania, the utilization of common bean accessions by plant breeders in their breeding programs is restricted due to lack of official reports or publications about these genetic resources (CIAT, 2008). More than 150 landraces are cultivated by small scale farmers but their data base is not yet officially reported. There is a considerable number of common beans conserved at the NPGRC in Tanzania involving many newly released varieties but both of them face several emerging threats including new persistent diseases, pests, environmental stresses and commercialization as well as socio-economic and political factors. Knowledge about the extent of

genetic diversity, identification, differentiation, and characterization of genotypes and populations provides information tool for detection of duplicates in the collection, their effective extension, a characterization and utilization in breeding programs (Beebe et al., 2000). Further, exploration of promising lines is important for genetic improvement of particular traits.) Therefore, this study focuses on the assessment of common bean accessions to detect desirable genotypes for breeding program. This allows the breeder to identify valuable traits or potentially valuable genotypes more efficiently and faster.

#### **MATERIALS AND METHODS**

#### Location of the study

The study was conducted at Sokoine University of Agriculture (SUA)-Morogoro, Tanzania at screen housed behind African Seed building located at latitude 6°84'795" S and 37°65'904" E at 543 m above the sea level. The study was for the period of December 2017 to October 2018.

#### **Genotypes collection**

A total of eighty-four common bean genotypes were collected from National Plant Genetic Resource Center (NPGRC) at Arusha, Uyole National Research Institute (UNRI) at Mbeya and SUA at Morogoro. They were then stored in a cold room before planting at Sokoine University of Agriculture, Department of Crop Science and Horticulture. The genotypes collected were diverse, representing a range of seed types involving seed coat color, size and shape. The accessions are indicated in Table 1.

#### Soil sampling and chemical analysis

Composite soil samples obtained were analyzed as described by (Carter, 1993). Bulk soil samples were taken at a depth of 0 - 20 cm on an area of  $2 \times 2 \text{ m}^2$ . Composite soil constituted nine sub-samples randomly collected from forestry area covering 1.0 ha. Sub-samples were thoroughly mixed, sterilized, air dried and ground to pass through an 8.0 mm mesh.

The 2.0 mm sieved composite soil samples were used for physical and chemical analyses in the laboratory. Composite soil samples were analyzed for pH, cation exchange capacity, exchangeable bases (Ca, K, Mg and Na), micronutrients (Fe, Zn, Mn and Cu), nitrogen, available P, particle size distribution and organic carbon (OC) as described by (Carter, 1993). The soil pH was determined in water at a soil: water ratio of 1:2.5 suspension using pH meter (Thomas,

1996). Electrical conductivity was measured in 1: 2.5 soil: water using the electric conductivity meter (Thomas, 1996). Cation exchange capacity (CEC) was determined by the ammonium-acetate saturation method and quantification of exchangeable bases: K, Ca, Na and Mg were determined from the ammonium-acetate filtrates following the Lindsay and Norvel (1978) methods. Exchangeable calcium (Ca) and magnesium (Mg) were determined by atomic absorption spectrophotometry whereas K and Na were extracted using ammonium acetate and analyzed by flame spectrophotometry.

The DTPA extractable Cu, Fe, Mn and Zn were determined by atomic absorption spectrophotometry (Lindsay and Norvel, 1998). Total nitrogen was determined by the micro-Kjeldahl digestion distillation method (Bremner and Mulvaney, 1982). Soil extractable P was determined by using the Bray-1-P method (Kuo, 1996) and colour was developed by the ascorbic acid-molybdate blue method Organic carbon was determined by the Walkley-Black wet combustion method. Particle size analysis was determined by the hydrometer method after dispersing the soil samples with sodium hexametaphosphate solution (Gee and Baunder, 1986). Soil textural classes were determined using the USDA textural class triangle (USDA, 1975).

## Screen house experimentation and agronomical practices

Eighty-four genotypes were arranged in a completely randomized design (CRD) and replicated three times. Before sowing, the 4 kg potted soil was watered and allowed to stay for one day. Four seeds were sown; thinning was done at age of 10 days after emergence. Irrigation by re-introducing trapped water (infiltrates) on bottomed trays was carried out regularly to maintain the moisture content.

#### **Data collection**

With the guide according to the International Board for Plant Genetic Resources (IBPGR) descriptors for Phaseolus vulgaris L. documentation (CIAT, 1987), a total of twenty traits were scored. Three (4) phenological traits were recorded viz. emergence (ED), days to flowering, days to 50% flowering days (DTFLO) and days to 90% maturity. Twelve qualitative traits including hypocotyl color (HYP.CLR), emerging cotyledon color (COT.CLR), growth habit (Gr.H), color of standard (CLRSTD), color of wings (CLRWNG), pod color (PDCLR) was also recorded. Other recorded traits included seed coat patterns (SCt.P), seed coat color (SCt.CLR), pod curvature (PDCUV), seed shape (SDSHP), brilliance of the seed (SD.BR) and seed size (SSize). Four (5) traits were quantitative which included; number of pods per plant (No. PDpP), pod length (PDL), locules per pod (LOC/PD), seeds per pod (SD/PD) and 100 seeds weight (100Ws).

#### Data analysis

#### **Distribution analysis**

Numerical values for the categorical traits from the 84 common bean genotypes were coded according to descriptor list (CIAT, 1987)]. Frequency distributions, minimum, maximum, standard deviation and correlations among traits were analyzed using the XLSTAT program, 2018.

#### Cluster analysis

Numerical values for the categorical traits from the 84 common bean genotypes were coded according to I descriptor list (CIAT, 1987). Data were analyzed by numerical taxonomy techniques, using XLSTAT 2018. Unweighted pair-group average (UPGA) of Hierarchical was used for cluster analysis and development of the dendrogram of the common bean genotypes based on 21 agro-morphological traits.

#### Principal component analysis

The phenotypic diversity of the traits was analyzed with the Pearson correlation aided with Principal component analysis (PCA) on ranged data with linear dimensionality reduction using XLSTAT (2018) to project the data into lower dimensions and to display genetically related genotypes in clusters (Mohammadi and Prasanna, 2003). The PCA was also used to show the traits which accounted for significant variation in the common bean germplasm.

#### **RESULTS**

#### Soil chemical analysis

The experimental forestry soils had medium to high chemical and sandy clay loam textural class as physical characteristics (Table 2). The analyzed composite forestry soil based on the selected soil parameters showed optimal condition that favors growth of common bean as described (Landon, 1991). Therefore, the forestry soils were suitable for production of common beans and other field crops like cereals.

Table 2: Physical-chemical properties of the experimental forestry soil

| Soil parameter   | Values                       | Remark (Landon, 1991)              |  |  |  |  |
|--|------------------------------|------------------------------------|--|--|--|--|

#### **Distribution of characters**

#### Phenological traits

After planting, a total of 34 (40.48%) and 32 (39.29%) common bean genotypes took five and six days respectively to emerge while 12 genotypes (14.29%) emerged early (4 days) and 5 genotypes (5.95%) emerged late (7 days). The maximum, minimum, mean and standard deviation values for the 21 agromorphological traits among the genotypes are shown in Table 3. The traits were significantly (P<0.01) different among the genotypes. Mean early flowering

days among genotypes was 22 days for 3 (3.57%) genotypes, mean late flowering days among genotypes was 30 days for 1 (1.19%) genotype and majority had mean flowering days of 25 days for 19 (22.62%) genotypes. Among the genotypes, the 90% maturity day ranged from 65 to 73 days whereby 3 (3.57%) genotypes matured early when it was 65 days, high number of genotypes (19) 22.62% matured full after 68 days and the late maturing genotype (1)1.19% was observed at 73 days averagely (Table 4).

Table 3: The maximum, minimum, mean and standard deviation values for the 21 agro-morphological traits.

#### **Quantitative traits**

Number of pods per plant ranged from 1.83 to 15.33. A range of pod length was 4.6 to 13.0 cm and number of locules per pod was 2 to 5. The number of seeds per pod ranged from 1.35 to 6.86 and the 100 seeds weight ranged from 15.4 g to 60.0 g (Table 3).

#### **Qualitative traits**

Predominantly emerging cotyledon color of most genotypes (82.14%) was green (COT.CLR), 8.33% was purple, 5.95% was very pale green, 2.38% was pinkish and 1.19% was reddish. Most genotypes (86.9%) had green colored hypocotyl (HYP.CLR), 7.14% of genotypes had purple color; while 4.76% were pale green colored hypocotyl. The predominant growth habit (Gr.H) was indeterminate bush with moderate climbing ability and pods distributed evenly up to the plant (40.48%), followed by indeterminate bush with semi-climbing main stem and branches (36.9%), then indeterminate bush with prostrate (14.29%), indeterminate bush with erect branches (7.14%) and determinate bush least (1.19%).

In freshly opened flowers, 48 genotypes (57.14%) had white predominant color of standard petals (CLRSTD). Others were white with lilac edges (34.52%) for 29 genotypes and purple (8.33%) for 7 genotypes. Most accessions (57.14%) had white colour of flower wings (CLRWG), while 34.52% were

white with carmine strips, and 8.33% purple. The predominant fully expanded immature pod color among 84 genotypes, 69 genotypes had green pod (82.14%). Others were carmine stripe on green (7.14%) for 6 genotypes, pale red stripe on green (5.95%) for 5 genotypes, and purple stripe on green (4.76%) for 4 genotypes as shown in Table 4. Fortyfour (44) common bean genotypes (52.4%) had slightly curved pods (PDCUV), 33 genotypes (39.3%) had straight pods and 7 genotypes (8.3%) were curved pods.

The dominant seed coat colour was maroon (26.2%) for 22 genotypes. Others were brown yellow 25% for 21 genotypes followed with, whitish seed coat color 13.1% for 11 genotypes, yellow to greenish yellow 9.5% for 8 genotypes, purplish seed coat color 7.1% for 6 genotypes, both brown and grey, brown to greenish seed coat colors 6% for 5 genotypes respectively, both brown, pale to black and pale cream to buff seed color 2.4% for 2 genotypes and were both green to olive and pinkish seed color least (1.2%) for 1 genotype. Thirty-six genotypes (42.9%) had no seed coat patterns. Also, 22 genotypes (26.2%) had stripped seeds, 18 genotypes (21.4%) had spotted bicolor seeds, 8 genotypes (8.3%) had speckled seeds and 1 genotype (1.2%) had constantly mottled seeds. The dominant seed shape was truncate fastigiated in 31 genotypes (36.9%) followed by the kidney shaped seed in 22 genotypes (26.2%), cuboid in 13 genotypes (15.6%), round

shaped seed in 12 genotypes (14.3%) and oval shaped seeds in 6 genotypes (7.1%). The predominantly seed size was medium in 53 genotypes which accounted of 63.10%, small seeded

genotypes were 17 (20.24%) and larger seeded genotypes were 14 (16.67%) (Table 4).

#### Phenotypic correlations among traits

Pair wise correlations among traits are shown in Table 5. The most strongly correlated traits were flowering days (FD) (r = 1) with 50% flowering days (50%FLWD), color of wings (W.CLR) (r = 1) with the color of standard (CLR.STD) and 100 seeds weight (r = 0.848, p<0.05) with seed size. Medium positive correlation was observed between cotyledon color trait (CCL) (r = 0.659, p<0.05) and the hypocotyl color

(HYP.CRL), but lowest positive correlation was between days of emergence (ED) (r=0.007) and number of seeds per pod (SDPD). The medium negative correlation (r=-0.494) between color of wings (W.CLR) and hypocotyl color was significant (p<0.05) similar to correlation between color of standard petals (STD.CLR) (r=-0.494) and hypocotyl color (H.CLR). The lowest negatively correlation was between 100 seeds weight and hypocotyl color (r=-0.004).

Table 5: Correlation coefficients among 21 morphological traits of common bean accessions from regions of Tanzania

#### Morphological diversity

#### Principal component analysis

The morphological characterization was required to describe the phenotypic variability in common bean genotypes collected from different regions of Tanzania. The PCA reduced the data to a few dimensions and explained 35.723% of total phenotypic variation in the germplasm as presented in Table 6. Eigen-values for these traits show that for the first component the highest absolute values corresponded to both flowering days, 50% flowering days and the 90% maturity days, as well as number of locules per pod, 100 seeds weight (g), brilliance of seeds, seed size and growth habit. For the second

component the highest values were for colour of standard petals and the wings, as well as the hypocotyl colour, the cotyledon colour and the colour of the pods. The spatial distribution of the common bean genotypes with the 90% maturity days, flowering days and low 100 seeds weight are in the I and II quadrant as reading clockwise in Figure 1. The genotypes *Belta 10, Nanka,* and *Mwolo-yellow* are exemplified for such dispersion. In quadrant III and IV clockwise, there are genotypes that are characterized by great 100 seeds weight, attaining early 90% maturity and early emergence and these genotypes include *Canadian wonder, Soya, Rukululana, Shona Egunia* and *Malima/Ndondo*.

Principal component axes 1 and 2 and traits with Eigen-values set arbitrarily above 0.2 (highlighted), explained 35.78% of total variation in the bean germplasm.

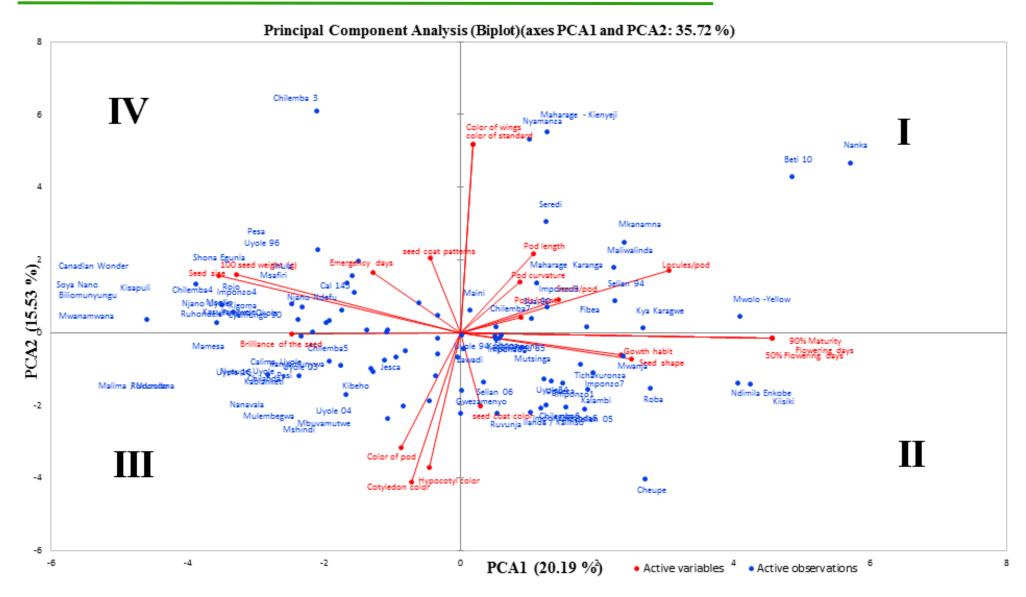

Figure 1: Dispersion of populations of common bean genotypes distributed across the regions of Tanzania based on two principal components (PC 1 and PC 2) of agro-morphological trait

#### Cluster analysis

Cluster analysis based on morphological and agronomical traits grouped genotypes into 2 main clusters (I and II) at 0.98 coefficient of similarity for 21 morphological and agronomical traits. The traits are days to emergence, cotyledon color, hypocotyl color, days to flowering, days to 50% flowering days to 90% maturity, color of wings, color of standard, color of pod, pod length (cm), brilliance of the seed, seed size, seed shape, seed coat color, seed coat patterns, number of locules per pod, pod curvature, growth

habit, number of pods per plant, number of seeds per pod and 100 seeds weight (g). The main cluster I comprised three (3) sub clusters namely sub-cluster A, B, and C makes a total of 82 common bean genotypes as they can be identified by reading the dendrogram ascending from the genotype named *Uyolee 04* to *Mkanamna*. The main cluster II comprises 2 genotypes as they can be identified by reading the dendrogram descending from the genotype named *Biliomunyungu* to *Kablanketi*. No sub cluster formed.

#### **DISCUSSION**

Genetic diversity of any food crop is an essential component in germplasm evaluation and as a prerequisite in conservation prospects. Common bean has an important role in dry land farming systems and provides high amount of crude protein used for human consumption and animal feed. The rational use of genotype collections requires a good about their characteristics. knowledge Well characterized and documented ex-situ genotype collections provide can consequently useful information to plant breeders. This aids researchers in identification of potential parents with desirable genes for incorporation into local cultivars for improved crop productivity. Morphological traits have long been the means of studying taxonomy and variability among common bean genotypes.

#### Phenotypic trait correlations.

Correlation matrix helps to determine pairs of characters that vary in the same or opposite direction and useful guide; especially for the plant breeders who may wish to associate a set of their desired traits in their breeding programs. The strongly correlated traits are possibly under the influence of the same genes or pleiotropic effects (Miko, 2008). There were strong correlations between some traits (Table 5), which allows for simultaneous selections and use of the related traits interchangeably. Practically, during bean improvement, if two or more strongly correlated traits are desired, they can both be selected simultaneously basing on one of the influential traits. For example, the positive correlations between seed size (r = 0.848, p<0.05) and 100 seed weight, indicates that the seed size can be used to determine grain weight and consequently yield. On the other hand, selection for relative 100 seed weight would lead to late flowering (r = -0.332, p<0.05), low locules per pod (r = -0.350, p<0.05) and number of seeds per pod (r = -0.228) since these traits were negatively correlated. The near to unit correlations (r = 1.00) of wing and standard petal colours suggests that these traits are controlled by one gene (pleiotropy) or are very closely linked (Miko, 2008).

#### Morphological diversity

#### Principal component analysis

PCA is the method of data reduction to clarify the relationships between two or more traits and to divide the total variance of original traits into a limited number of uncorrelated new variables (Wiley, 1980). Based on morphology, the PCA results (Table 6 and Figure 1) illustrated the overall picture of the pattern of genetic diversity of the common bean genotypes. The *Eigen value* formed the basis for identifying component axes (PCA1 and PCA 2) (Panthee et al., 2006) with scores, cut off level arbitrarily set above 0.2 to show traits, which explained most variations in

the common bean accessions. The first summarizes most of the variability present in the collected data relative to the remaining PCs, hence recorded the highest Eigen value 0.415 (Table 6) and accounted for 20.194 % of the total variation. For instance, considering only PCA Eigen values in PC1 for both quadrants I and II clockwise, most genotypes had late flowering days, 50% flowering days and 90% maturity days. This axis indicates that most attributed accessions were to the positive phenological traits complemented with the number of locules per pod and the growth habit. This suggests that the traits above are the most important for future common bean characterization and conservation studies. In other studies, in common bean, Okii et al. (2014) characterized 284 landraces from Uganda, using the IPBRI descriptor for P. vulgaris and identified suitable traits for breeding purposes.

#### Cluster analysis

The cluster analysis for the morphological traits included in this study placed common bean genotypes into two main clusters with sub clusters for main cluster I (Figure 2). These results agreed with Blair et al. (2010) who also reported that in cluster analysis cultivars are grouped together with the greater morphological similarities. Clusters were also grouped together for the improved and landraces signifying that they are less variable in their morphological traits.

For instance, in the main cluster I sub-cluster A, the improved variety of Zawadi, Mshindi, Pasi and Jesca were placed together with the landraces of Kanyamunywa, Rukurulana and Kashiransoni. This indicates that they consisted of the heterogeneous group of accessions with same origin. The diversity of the common bean genotypes observed in this study could be in part due to farmers' customary seed exchanges as it was reported by CIAT (2005) since the exchange of seed materials is not unique to farmers. Further, Blair et al (2010) reported farmers' preference for many landraces and diversified bean types are used for various agronomic and cultural reasons. In addition, varieties preferred for home cooking with unique seed colours are selected for sale in the local markets, hence, increasing bean diversity across regions of Tanzania. Frequent mutations and genetic recombination are the other possible causes of high diversity of the common bean genotypes studied.

#### CONCLUSION

Common bean accessed displayed a considerable range of morphological diversity for most of the agromorphological traits studied. Phenological traits of days to emergence, days to flowering, days to 50% flowering and days to 90% flowering exhibited a strong positive correlation as those of qualitative traits

like color of standard petal and color of wings. Seed size strongly positive correlated with 100 weight traits which determine the yield potential of a variety. A significant variation accounted in the principal component analysis on the collected common bean genotypes was contributed by phenological traits (days to emergence, days to flowering, days to 50% flowering and days to 90% flowering) for the PCA1 and qualitative traits (colour of standard petal and colour of wings) for the PCA2. Further, both improved and landrace genotypes were clustered in the same group hence clarifying that they're heterogeneous but with the same origin. Therefore, we recommend that morphological traits were useful for the preliminary evaluation and can be used as a general approach of assessing variability or variation morphologically distinct common bean genotypes; molecular analysis of the collected common bean genotypes is recommended to be carried out in order to detect possible genetic relationships of this material, as a further step.
